## Introduction to Bayesian Data Analysis Tutorial 5

- (1) Problem 6.1 (Hoff) Poisson population comparisons: The data files menchild30bach.txt and menchild30nobach.txt contain data on the number of children born to men in their 30s with and without bachelor's degrees respectively. Let the average number of children in each group be  $\theta_A$  and  $\theta_B$  respectively. Assume Poisson sampling models for the two groups and let  $\theta_A = \theta$  and  $\theta_B = \theta \times \gamma$ . In this parameterization,  $\gamma$  represents the relative rate  $\theta_B/\theta_A$ . Let  $\theta \sim \text{gamma}(a_\theta, b_\theta)$  and let  $\gamma \sim \text{gamma}(a_\gamma, b_\gamma)$ .
  - (a) Are  $\theta_A$  and  $\theta_B$  independent or dependent under this prior distribution? In what situations is such a joint prior distribution justified?
  - (b) Obtain the form of the full conditional distribution of  $\theta$  given  $\mathbf{y}_A$ ,  $\mathbf{y}_B$  and  $\gamma$ .
  - (c) Obtain the form of the full conditional distribution of  $\gamma$  given  $\mathbf{y}_A$ ,  $\mathbf{y}_B$  and  $\theta$ .
  - (d) Set  $a_{\theta} = 2$  and  $b_{\theta} = 1$ . Let  $a_{\gamma} = b_{\gamma} \in \{8, 16, 32, 64, 128\}$ . For each of these five values, run a Gibbs sampler of at least 5,000 iterations and obtain  $E[\theta_B \theta_A | \mathbf{y}_A, \mathbf{y}_B]$ . Describe the effects of the prior distribution for  $\gamma$  on the results.
- (2) Problem 6.2 (Hoff) Mixture model: The file glucose.dat contains the plasma glucose concentration of 532 females from a study on diabetes.
  - (a) Make a histogram or kernel density estimate of the data. Describe how this empirical distribution deviates from the shape of a normal distribution.
  - (b) Consider the following mixture model for these data: For each study participant there is an unobserved group membership variable  $X_i$  which is equal to 1 or 2 with probability p and 1-p. If  $X_i=1$  then  $Y_i \sim \operatorname{normal}(\theta_1, \sigma_1^2)$ , and if  $X_i=2$  then  $Y_i \sim \operatorname{normal}(\theta_2, \sigma_2^2)$ . Let  $p \sim \operatorname{beta}(a,b)$ ,  $\theta_j \sim \operatorname{normal}(\mu_0, \tau_0^2)$  and  $1/\sigma_j \sim \operatorname{gamma}(\nu_0/2, \nu_0\sigma_0^2/2)$  for both j=1 and j=2. Obtain the full conditional distributions of  $X_1, ..., X_n, p, \theta_1, \theta_2, \sigma_1^2$  and  $\sigma_2^2$ .
  - (c) Setting a=b=1,  $\mu_0=120$ ,  $\tau_0^2=200$ ,  $\sigma_0^2=1000$  and  $\nu_0=10$ , implement the Gibbs sampler for at least 10,000 iterations. Let  $\theta_{(1)}^{(s)}=\min\left\{\theta_1^{(s)},\theta_2^{(s)}\right\}$  and  $\theta_{(2)}^{(s)}=\max\left\{\theta_1^{(s)},\theta_2^{(s)}\right\}$ . Compute and plot the autocorrelation functions of  $\theta_{(1)}^{(s)}$  and  $\theta_{(2)}^{(s)}$ , as well as their effective sample sizes.
  - (d) For each iteration s of the Gibbs sampler, sample a value  $x \sim \text{binary}(p^{(s)})$ , then sample  $\tilde{Y}^{(s)} \sim \text{normal}(\theta_x^{(s)}, \sigma_x^{2(s)})$ . Plot a histogram or kernel density estimate for the empirical distribution of  $\tilde{Y}^{(1)}, ..., \tilde{Y}^{(S)}$ , and compare to the distribution in part a). Discuss the adequacy of this two-component mixture model for the glucose data.
